HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Enantio-enriched CPL-active helicene-bipyridine-rhenium complexes

Nidal Saleh,^a Monika Srebro,^b Thibault Reynaldo,^a Nicolas Vanthuyne,^c Loïc Toupet,^a Victoria Y. Chang,^d G. Muller,^d J. A. Gareth Williams,^e Christian Roussel,^c Jochen Autschbach,^{*f} Jeanne Crassous^{*a}

The incorporation of a rhenium atom within an extended helical π -conjugated bi-pyridine system impacts the chiroptical and photophysical properties of the resulting neutral or cationic complexes, leading to the first examples of rhenium-based phosphors that exhibit circularly polarized luminescence.

2,2'-Bipyridine (bipy) derivatives are widely used N,N' -bidentate ligands in coordination chemistry, giving access to a great variety of complexes.¹ The luminescence properties of d^6 transition metal polypyridyl complexes have been increasingly studied for the development of new metal-based luminescent materials and sensing probes.² Among them, $[\text{Re}(N,N')(\text{CO})_3\text{X}]^{0/+}$ complexes (X = halide, pyridyl (py) or isocyanide (CNR)) exhibit room-temperature (RT) phosphorescence from triplet metal-to-ligand (ML) and/or intraligand charge-transfer (ILCT) states.^{3,4} Such d^6 -complexes find applications as electroswitchable emissive systems,^{5a} cellular imaging agents,^{5b,c} chromophores for photoredox chemistry,^{5d} etc. It would therefore be of great interest to develop chiral analogues⁶ in order to benefit from the chiral version of emission, namely circularly polarized luminescence (CPL) which may potentially be used in cryptography or for 3D-displays.^{7,8}

In this communication, we describe the synthesis of tricarbonyl Re^{I} complexes of general formula $[\text{Re}(N^{\wedge}N')(\text{CO})_3\text{X}]^{0/+}$ (X = halide, pyridyl or isocyanide) with $N^{\wedge}N'$ being either achiral 3-(2-pyridyl)-4-aza[4]-helicene (**1a**) or chiral 3-(2-pyridyl)-4-aza[6]-helicene (M - and P -**1b**) (Scheme 1). The stereochemical features of these novel d^6 -complexes are presented in detail. The chiroptical properties of enantio-enriched samples and the non-polarized and circularly polarized phosphorescence were measured experimentally and analyzed using quantum-chemical calculations.

Re^{I} -complex **2a** was obtained in 85% yield as a yellow-orange precipitate upon refluxing a solution of **1a**^{8g} and $\text{Re}(\text{CO})_5\text{Cl}$ in toluene for 5 hours (Scheme 1). It was fully characterized by multinuclear NMR spectroscopy (one set of peaks), by elemental analysis, UV-vis and emission spectroscopies. As compared to ligand **1a**, the ¹H NMR spectrum of **2a** shows strongly deshielded signals (except for H^2 , H^{12} and H^6) with $\Delta\delta$ up to +0.8 ppm for H^5 (see Supporting Information, SI). The UV-vis spectrum of ligand **1a** in CH_2Cl_2 displays a strong band at 295 nm ($\epsilon > 50 \times 10^3 \text{ M}^{-1} \text{ cm}^{-1}$), accompanied by several structured bands of lower intensity between 300 and 400 nm. Meanwhile, complex **2a** shows several absorption bands between 230 and 370 nm ($\epsilon \sim 30\text{--}43 \times 10^3 \text{ M}^{-1} \text{ cm}^{-1}$) that can be assigned to intraligand $\pi\text{--}\pi^*$ transitions and a broad, low-energy absorption band between 370

and 480 nm ($\lambda_{\text{max}} = 398 \text{ nm}$, $\epsilon = 12700 \text{ M}^{-1} \text{ cm}^{-1}$) related to the incorporation of the Re^{I} metal and predominantly assigned as ILCT with small contributions of MLCT character (*vide infra*). The absorption maximum at 398 nm appears red-shifted compared to the corresponding band in $\text{Re}(\text{2,2'-bpy})(\text{CO})_3\text{Cl}^{\text{3f}}$ (350 nm) indicating extended π -conjugation.

Scheme 1. Synthesis of neutral and charged rhenium complexes **2a-4a** and enantio-enriched $(M,ARE)\text{-2b}^1$, $(M,CRe)\text{-2b}^2$ and $(M,ARE^*)\text{-3b}^{1,2}$ from respectively [4]helicene-bipy, **1a** and M -[6]helicene-bipy, **M-1b**. i) $\text{Re}(\text{CO})_5\text{Cl}$, toluene, reflux; ii) AgOTf , EtOH/THF , then 2,6-dimethylphenyl isocyanide, THF, NH_4PF_6 , 75–80%; iii) AgBF_4 , CH_3CN , reflux then pyridine, THF, 80%. X-ray crystallographic structures of racemic **2b}^2**, **3a** and **4a** (only (M,CRe) stereoisomers are shown).¹⁰

Re^{I} complex **2a** is red-phosphorescent in CH_2Cl_2 at RT ($\lambda_{\text{max}}^{\text{phos}} = 678 \text{ nm}$, $\phi = 0.11\%$, $\tau = 25 \text{ ns}$, see SI). The phosphorescence originates from the triplet charge-transfer state. It is facilitated by spin-orbit coupling at the rhenium heavy atom and bathochromically shifted compared to that of $\text{Re}(\text{2,2'-bpy})(\text{CO})_3\text{Cl}$ ($\lambda_{\text{max}}^{\text{phos}} = 610 \text{ nm}$).^{3f} At 77 K, the phosphorescence of **2a** is significantly shifted to shorter wavelengths ($\lambda_{\text{max}}^{\text{phos}} = 550 \text{ nm}$, $\tau = 7.9 \mu\text{s}$). Such a hypsochromic shift is usually explained by inversion in energies of $^3\pi\text{--}\pi^*$ and $^3\text{MLCT}$ triplet states and/or by rigidification of the system.³ Note that as usual in this class of complexes, the quantum yield at RT is rather low.³ In comparison, charged complexes of formula $[\text{Re}(N^{\wedge}N')(\text{CO})_3\text{py}]^+$ or $[\text{Re}(N^{\wedge}N')(\text{CO})_3\text{CNR}]^+$ typically display superior luminescence efficiency due to a stronger ligand field. For this reason, complexes **3a** and **4a** were prepared in good yields from **1a**, according to Scheme 1. They were fully characterized by multinuclear NMR spectroscopy, elemental analysis, UV-vis spectroscopy, emission and X-ray crystallography. The **3a** and **4a** compounds crystallize in $Fdd2$ and $P2_1/n$ centrosymmetric space groups respectively (Scheme 1). At this stage, it is worth noting that complexes **2a-4a** are chiral at the rhenium centre,^{9,#} since the

Re atoms adopt a slightly distorted octahedral geometry, with three carbonyl groups being *fac*-oriented around the Re^I, as classically seen in such rhenium(I) tricarbonyl diimine complexes.³ The equatorial planes are defined by the chelate bipyridine ligand and two *trans* carbonyls. A third carbonyl and either the chlorine, the isocyanide or the pyridine are placed in the apical positions. Note that in structures **3a,4a** the [4]helicene-bpy ligand exhibits a helicity angle (defined as angle between the terminal rings of the helicene moiety) of ~35° and the cyanide and pyridine ligand are directed towards it, thus defining the (*P,A*^{Re}) and (*M,C*^{Re}) stereochemistry.¹⁰ However, in solution, the helicene is not configurationally stable, and the Re center readily epimerizes (*vide infra*). As expected, the charged complexes displayed improved photophysical properties with similar UV-visible and emission spectra as for **2a** (see SI), but with higher quantum yields (**3a**: 16%; **4a**: 8.3%). These results prompted us to prepare tricarbonylrhenium(I) complexes bearing a configurationally stable enantiopure [6]helicene-bipy ligand.

Racemic **1b** was reacted with Re(CO)₅Cl in refluxing toluene for 5 hours, yielding after purification by column chromatography two distinct diastereomeric Re(I) complexes (**2b**¹ and **2b**², with 28% and 52% yields, respectively) as evidenced by ¹H and ¹³C NMR spectroscopy (for example H¹⁵: 6.7 ppm for **2b**¹ and 6.9 ppm for **2b**², see SI). Complex **2b**² crystallizes in a centrosymmetric space group (P2₁/C) in which two enantiomeric structures, namely (*M,C*^{Re})- and (*P,A*^{Re})-**2b**² are present (Scheme 1).¹⁰ Note that a substantial distortion results from the bite angles between the chelating N atoms of the helicenic ligand, the rhenium centre and the chloride ligand ranging between 82.6 and 84.3°. In complex **2b**² the chlorine atom is directed towards the helicene moiety, whereas it directs outwards from the helicene core in the enantiomeric complexes (*M,A*^{Re}) and (*P,C*^{Re})-**2b**¹. The helicity of the aza[6]helicene moiety ranges between 47.0-66.2°, which is typical for aza[6]helicene derivatives (58° for carbo[6]helicene).⁸ Finally, complexation with Re affords an extended π -conjugation over the whole molecule, as evidenced by the small NCCN dihedral angles between the two chelating pyridine moieties (-3.1-6.0°). The extended π -conjugation and the metal-ligand interaction are evidenced by UV-vis spectroscopy since **2b**^{1,2} display similar UV-vis spectra with a set of several bands between 330 and 450 nm ($\epsilon \sim 7\text{--}25 \times 10^3 \text{ M}^{-1} \text{ cm}^{-1}$) that are bathochromically shifted and more intense compared to ligand **1b**, together with a very weak band observed between 450 and 500 nm (see Figure S21). Calculations at the BHLYP/SV(P) level with the continuum solvent model for CH₂Cl₂ reproduce well these data and show that the low-energy band of the spectrum is dominated by an ILCT transition, $\pi(\text{helicene}) \rightarrow \pi^*(\text{N}^{\wedge}\text{N}')$, while the medium-energy bands are mostly π -to- π^* 'CT-like' transitions localized within the helicene moiety (*vide infra*, SI) in agreement with assignments of absorption spectra of related rhenium(I) systems, in particular for complexes with large π -conjugated ligands.^{4c-e} The overall contribution of the Re orbitals is low, meaning that the primary effect of the metal is to rigidify the system and induce strong charge-transfer from the helical π -system to the bipy N[^]N' part of the ligand. The simulated spectral shapes and band positions agree well with experiment. It is possible, though, that the overall involvement of Re orbitals in the absorption

transitions is somewhat underestimated by the BHLYP functional (*vide infra*). Re^I complexes **2b**^{1,2} are red-phosphorescent emitters in CH₂Cl₂ at RT (**2b**¹: $\lambda_{\text{max}}^{\text{phos}} = 680 \text{ nm}$, $\phi = 0.13\%$, $\tau = 27 \text{ ns}$; **2b**²: $\lambda_{\text{max}}^{\text{phos}} = 673 \text{ nm}$, $\phi = 0.16\%$, $\tau = 33 \text{ ns}$; for details see SI). At 77 K, these complexes display phosphorescence at shorter wavelengths (**2b**¹: $\lambda_{\text{max}}^{\text{phos}} = 560 \text{ nm}$, $\tau = 46 \text{ }\mu\text{s}$; **2b**²: $\lambda_{\text{max}}^{\text{phos}} = 554 \text{ nm}$, $\tau = 43 \text{ }\mu\text{s}$) (*vide supra*). Note that the emission properties of diastereomers **2b**^{1,2} are only slightly different and (for τ and ϕ) within the uncertainty in the measurements (see SI).

Enantiopure complexes (*M,A*^{Re})-**2b**¹ and (*M,C*^{Re})-**2b**² were then prepared from enantiopure *M*-**1b** (their mirror-images (*P,C*^{Re})-**2b**¹ and (*P,A*^{Re})-**2b**² from *P*-**1b**). Enantiopure complexes **2b**^{1,2} display similar molar rotation (MR) values to **1b** in CH₂Cl₂ {(*P,C*^{Re})-(+)-**2b**¹: $[\phi]_{\text{D}}^{25} = +9260 \text{ degree cm}^2/\text{dmol}$ ($\pm 5\%$), calc. BHLYP +12721; (*P,A*^{Re})-(+)-**2b**²: $[\phi]_{\text{D}}^{25} = +10260$ ($\pm 5\%$), calc. BHLYP +11888 degree cm²/dmol; *P*-(+)-**1b**:^{8g} $[\phi]_{\text{D}}^{25} = +12000$ ($\pm 5\%$), calc. BHLYP +14176, see SI}. The ECD spectrum of *P*-**2b**¹ shows a strong negative band around 261 nm ($\Delta\epsilon = -114 \text{ M}^{-1} \text{ cm}^{-1}$) and strong positive ones at 350 (+81 M⁻¹ cm⁻¹) and 368 nm (+76 M⁻¹ cm⁻¹) accompanied by weaker bands between 380 and 450 nm (20-40 M⁻¹ cm⁻¹) and an even weaker one around 480 nm but of opposite sign ($\Delta\epsilon \sim -0.6 \text{ M}^{-1} \text{ cm}^{-1}$). Diastereomeric complex (*P,A*^{Re})-(+)-**2b**² exhibits the same ECD active bands as **2b**¹ but they are more intense. A comparison with experimental ECD of **1a** enantiomers is displayed in Figure 1. The calculated (BHLYP/SV(P) with the continuum solvent model for CH₂Cl₂) spectra of **2b**^{1,2} qualitatively agree well with the experimental results (Figure 3 and S5). A detailed analysis of dominant excitations in the low- and medium-energy parts of the simulated spectra of **2b**^{1,2} indicates that the low-energy tail of the first positive ECD band is caused by excitation no. 1 calculated at *E* = 3.3 eV (375 nm). The excitation can be assigned as a π - π^* ILCT transition involving the helicene-centered HOMO (H), H-1, and the bipyridine N[^]N'-centered LUMO (L), for example for **2b**¹: H-L 51% and H-1-L 18% (see Figure 3 and SI). The second dominant **2b**^{1,2} excitation is no. 5 calculated at *E* = 3.8 eV (330 nm) with the strongest rotatory strength. It involves two main contributions from π and π^* orbital pairs localized mostly in the helicene moiety: H-L+1 and H-1-L+1 (respectively 43% and 25% for **2b**¹). The excitation reveals partial CT character.

A novel aspect of these rhenium(I) helicene-based complexes is that they are CPL active (Figure 2, top panels).^{7,8} To the best of our knowledge, these are the first examples of CPL-active phosphorescent rhenium complexes. Indeed phosphorescent (*P,A*^{Re}) and (*M,C*^{Re})-**2b**² enantiomers displayed mirror-imaged CPL spectra (Figure 2) with opposite g_{lum} values ((*P,A*^{Re})-**2b**²: +3.1 $\times 10^{-3}$ and (*M,C*^{Re})-**2b**²: -2.8 $\times 10^{-3}$) around the emission maximum (~670 nm). These values are of the same order as for the **1b** ligand enantiomers ($g_{\text{lum}} \sim \pm 10^{-3}$) but lower than those of previously published platina[6]helicenes ($g_{\text{lum}} \sim \pm 10^{-2}$),^{8e} because Re orbitals are less involved in the helical π -system of the molecule (*vide supra*).

Figure 1. Experimental CD spectra of enantiopure *M*-(-) (dotted red) and *P*-(+)-**1b** (plain red) and their corresponding enantiopure Re^{I} complexes (M, A^{Re})-(-)-**2b**¹ and (P, C^{Re})-(+)-**2b**¹ (light blue) and (M, C^{Re})-(-)-**2b**² and (P, A^{Re})-(+)-**2b**² (dark blue). Inset: CD spectra of (-) and (+)-**2b**¹ between 450-550 nm.

In order to improve the efficiency of the chiroptical and photophysical properties, tricarbonyl-isocyanide-helicene-bipy- Re^{I} complex **M-3b** was prepared (see Scheme 1) in 75% yield from either (M, A^{Re})-(-)-**2b**¹ or (M, C^{Re})-(-)-**2b**². In this complex, the Re center appeared labile and **3b** was obtained as a mixture of (M, A^{Re})-**3b**¹ and (M, C^{Re})-**3b**² as observed by ^1H and ^{13}C NMR spectroscopy (diastereomeric ratio 50:50, see Figure S27) regardless of the diastereomeric purity of the starting compound used (either **2b**¹ or **2b**² or **2b**^{1,2}). Nevertheless, as expected, this diastereomeric mixture displayed an improved quantum yield ($\lambda_{\text{max}}^{\text{phos}} = 598 \text{ nm}$, $\phi = 6\%$, $\tau = 79 \mu\text{s}$; see SI) as compared to **2b**^{1,2}. The UV-vis spectrum of **3b**^{1,2} displays the same shape as **2b**¹ (see Figure S21). Compared to (P, C^{Re})-**2b**¹ and (P, A^{Re})-**2b**², cationic diastereomeric mixture of Re^{I} complexes **P-3b**^{1,2} displays an additional positive CD-active band around 450 nm ($\Delta\epsilon = 17.5 \text{ M}^{-1} \text{ cm}^{-1}$). As for **2b**^{1,2}, this latter band does not involve the Re center, but corresponds to the H-L transition (>74%) with strong charge transfer from the π -helicene to the bipy moiety, as evidenced by BHLYP calculations (see Figure 3 and SI). The appearance of the 450 nm band is caused mainly by a bathochromic shift of the first singlet excitation. This charge transfer excitation is likely responsible for the enhancement of molar rotations as compared to **2b**^{1,2} {(P, A^{Re})-(+)-**3b**: $[\phi]_{\text{D}}^{25} = 15040 (\pm 5\%)$ ($C = 8.8 \times 10^{-5} \text{ M}$, CH_2Cl_2); (M, A^{Re})-(-)-**3b**: $[\phi]_{\text{D}}^{25} = -14230 (\pm 5\%)$ ($C = 9.7 \times 10^{-5} \text{ M}$, CH_2Cl_2); calc. BHLYP Boltzmann average for **3b**^{1,2} conformers is +14034 degree cm^2/dmol for the *P*-isomers, see SI}.

Quantum-chemical calculations of luminescence properties have been performed for **2b**^{1,2} and **3b**^{1,2}. The results support the experimental assignments: The energies of $\text{T}_1 \rightarrow \text{S}_0$ phosphorescence transitions ($\sim 2.1 \text{ eV}$) are similar for both **2b**^{1,2} and **3b**^{1,2} and agree fairly well with the experimental data (Table S5). An overestimation of the calculated versus measured energies is consistent with a blue-shift of calculated **2b**^{1,2} and **3b**^{1,2} absorption and CD spectra. The emission energies from spin-orbit (SO) calculations agree with non-SO calculations but the former allow predictions of the phosphorescence lifetimes. Application of the BHLYP functional along with the Tamm-Dancoff approximation (see SI) resulted in much too high emission lifetimes (Table S6). As the involvement of Re orbitals

facilitates the formally spin-forbidden $\text{T}_1 \rightarrow \text{S}_0$ phosphorescence transitions via spin-orbit coupling, decreasing the corresponding lifetimes, too high τ calculated with BHLYP may indicate that the metal orbital contributions to the frontier MOs are somewhat too small. The performance of a given functional for singlet vs. triplet transitions is not necessarily the same. When applying a computational protocol for emission lifetimes devised recently by Mori *et al.*¹¹ for organometallic complexes (full TDDFT with the B3LYP functional), a dramatic improvement of the lifetimes and some lowering of the emission energies (to $\sim 1.9 \text{ eV}$) was obtained (Table S7), which correlates with increased participation of Re orbitals in the frontier MOs at the triplet geometries. Notably the experimental trend of an increase in emission lifetime by roughly an order of magnitude when going from **2b**^{1,2} to **3b**^{1,2} is correctly reproduced with B3LYP and qualitatively consistent with lesser metal orbital participation (lesser MLCT character) in the T_1 emission transitions for **3b**^{1,2} as compared to **2b**^{1,2} (see SI).^{S,4a,b}

Figure 2. CPL (upper curves within each panel) and total luminescence (lower curves within each panel) spectra of *M*-(-)-**1b** (top left red), *P*-(+)-**1b** (top left black), *M*-(-)-**2b**¹ (top right red), *P*-(+)-**2b**² (top right black), *M*-(-)-**3b**^{1,2} (bottom left red), *P*-(+)-**3b**^{1,2} (bottom left black) in degassed CH_2Cl_2 solution (1 mM) at 295 K, upon excitation at 400, 456-461, and 458-468 nm, respectively.

Finally, mirror-imaged CPL spectra were obtained in CH_2Cl_2 for (M, A^{Re})-**3b**^{1,2} and (P, A^{Re})-**3b**^{1,2} (Figure 2) with respective g_{lum} values of -0.0015 and +0.0013. Overall, cationic Re^{I} complexes display similar CPL characteristics as neutral ones, but combined with a higher quantum yield, the polarized emitted light is stronger. Although the Re d orbitals are not strongly involved in the electronic π systems of these novel metallo-helicenes, the metal helps to increase the π -conjugation pathway and promotes charge transfer excitations within the π -helical ligand. In addition, the presence of the rhenium heavy atom makes these complexes chiral phosphors with unprecedented CPL activity.

In conclusion, the first CPL-active rhenium complexes have been prepared by coordination of enantiopure [6]helicene-bipyridine type ligands. Their chiroptical and photophysical properties (optical rotation, electronic circular dichroism, non-polarized and circularly polarized luminescence, quantum yields, phosphorescence lifetimes) have been studied and analyzed with the help of quantum-chemical calculations.

[#] Note that enantiopure (+) and (-) complexes $(1a)Re(CO)_2Br$ were prepared by chiral HPLC and they displayed very weak CD activity ($\Delta\epsilon_{max} = 20 M^{-1} cm^{-1}$, see Figure S23).

^S The direct comparison between experimental and calculated lifetimes must be treated with some caution, as the former are also affected by non-radiative decay pathways, which may be non-negligible even at 77 K. We assume that the non-radiative decay rates for the complexes are similar under these conditions.

J.* 2013, **19**, 13418; e) R. Horvath, M. G. Fraser, S. A. Cameron, A. G. Blackman, P. Wagner, D. L. Officer, K. C. Gordon, *Inorg. Chem.* 2013, **52**, 1304.

⁵ Selected: a) K. M. C. Wong, S. C. F. Lam, C. C. Ko, N. Y. Zhu, V. W. W. Yam, S. Roue, C. Lapinte, S. Fathallah, K. Costuas, S. Kahlal, J.-F. Halet *Inorg. Chem.* 2003, **42**, 7086; b) A. W.-T. Choi, V. M.-W. Yim, H.-W. Liu, K. K.-W. Lo, *Chem. Eur. J.* 2014, **20**, 9633; c) S. Clède, F. Lambert, C. Sandt, Z. Gueroui, M. Réfrégiers, M.-A. Plamont, P. Dumas, Anne Vessières, C. Policar *Chem. Commun.* 2012, **48**, 7729; d) H. Tsubaki, A. Sekine, Y. Ohashi, K. Koike, H. Takeda, O. Ishitani, *J. Am. Chem. Soc.* 2005, **127**, 15544.

⁶ Chiral and emissive rhenium complexes are still very rare, see for example: a) Y. H. Zhou, J. Li, T. Wu, X. P. Zhao, Q. L. Xu, X. L. Li, M. B. Yu, L. L. Wang, P. Sun, Y. X. Zheng, *Inorg. Chem. Commun.* 2013, **29**, 18; b) M. Q. Sans, P. Belser, *Coord. Chem. Rev.* 2002, 229, 59.

⁷ H. Maeda, Y. Bando, *Pure Appl. Chem.* 2013, **85**, 1967.

⁸ Selected examples of CPL active helicenes: a) J. E. Field, G. Muller, J. P. Riehl, D. Venkataraman, *J. Am. Chem. Soc.* 2003, **125**, 11808; b) Y. Sawada, S. Furumi, A. Takai, M. Takeuchi, K. Noguchi, K. Tanaka, *J. Am. Chem. Soc.* 2012, **134**, 4080; c) K. E. S. Phillips, T. J. Katz, S. Jockusch, A. J. Lovinger, N. J. Turro, *J. Am. Chem. Soc.* 2001, **123**, 11899; d) T. Kaseyama, S. Furumi, X. Zhang, K. Tanaka, M. Takeuchi, *Angew. Chem., Int. Ed.* 2011, **50**, 3684; e) C. Shen, E. Anger, M. Srebro, N. Vanthuyne, K. K. Deol, T. D. Jefferson Jr., G. Muller, J. A. G. Williams, L. Toupet, C. Roussel, J. Autschbach, R. Réau, J. Crassous, *Chem. Sci.* 2014, **5**, 1915; f) K. Nakamura, S. Furumi, M. Takeuchi, T. Shibuya, K. Tanaka, *J. Am. Chem. Soc.* 2014, **136**, 5555; g) N. Saleh, B. Moore, II, M. Srebro, N. Vanthuyne, L. Toupet, J. A. G. Williams, C. Roussel, K. K. Deol, G. Muller, J. Autschbach, J. Crassous, *Chem. Eur. J.*, 2015, **21**, 1673.

⁹ Enantiopure "chiral at rhenium" complexes are still very rare. Selected examples: a) S. J. Lee, W. Lin, *J. Am. Chem. Soc.* 2002, **124**, 4554; b) F. Bock, F. Fischer, W. A. Schenk, *J. Am. Chem. Soc.* 2006, **128**, 68; c) J. -D. Chen, F. A. Cotton, *J. Am. Chem. Soc.* 1991, **113**, 2509; d) J. H. Merrifield, C. E. Strouse, J. A. Gladysz, *Organometallics* 1982, **1**, 1204; e) W. E. Buhro, A. Wong, J. H. Merrifield, G. -Y. Lin, A. C. Constable, J. A. Gladysz, *Organometallics* 1983, **2**, 1852; f) P. R. Lassen, L. Guy, I. Karame, T. Roisnel, N. Vanthuyne, C. Roussel, X. Cao, R. Lombardi, J. Crassous, T. B. Freedman, L. A. Nafie, *Inorg. Chem.* 2006, **45**, 10230; g) F. De Montigny, L. Guy, G. Pilet, N. Vanthuyne, C. Roussel, R. Lombardi, T. B. Freedman, L. A. Nafie, J. Crassous, *Chem. Commun.* 2009, 4841; h) J. W. Faller, A. R. lavoie, *Organometallics* 2000, **19**, 3957; i) W. K. Rybak, A. Skarzynska, T. Glowiak, *Angew. Chem. Int. Ed.* 2003, **42**, 1725; j) C. M. Alvarez, R. Carrillo, R. Garcia-Rodriguez, D. Miguel, *Chem. Commun.*, 2011, 12765; k) E. Tazacs, A. Escande, N. Vanthuyne, C. Roussel, C. Lescop, E. Guinard, C. Latouche, A. Boucekkine, J. Crassous, R. Réau, M. Hissler, *Chem. Comm.* 2012, **48**, 6705.

¹⁰ For the stereochemical descriptors see SI and A. von Zelewsky, *Stereochemistry of Coordination Compounds*, J. Wiley & Sons, Chichester, 1996.
